0.2 Introduction

Cervical cancer happens when cells in the cervix, the lower part of the uterus that connects to the vagina, start to become abnormal. While it isn't perfectly clear what sparks the cervical cells to change their DNA, it is certain that human papilloma virus, or HPV, plays a role. The early stages of cervical cancer generally show no signs or symptoms. Hence it is very important to be able to detect it sooner. The paper offers a thorough examination of various local interpretability techniques used to elucidate the risk factors linked with cervical cancer. Its aim is to support healthcare professionals utilizing AI by providing insights into the most suitable explanation methods for specific situations. The framework proposed in the paper will be assessed to gauge the effectiveness of different explanations in assessing cervical cancer risk, and to determine how various explanations can be tailored to different patient scenarios. Additionally, the paper will introduce an empirical approach for calculating the faithfulness metric of different machine learning interpretability methods. This approach involves analyzing feature and rank agreement, and ensuring that removing the top N features, as predicted by local explanations, does not significantly impact model performance.

0.3 Scope of Reproducibility

The original paper focuses on evaluating different explanation methods for assessing cervical cancer risk. It aims to provide insights into the quality and suitability of these explanations in a healthcare context. The contribution lies in offering a systematic framework for interpreting model predictions and assessing the performance of various explanation techniques. The scope of reproducibility in the project draft involves replicating the evaluation of explanation methods conducted in the original paper. This includes implementing the systematic approach for interpreting model predictions and comparing the performances of different explanation methods in the context of cervical cancer risk assessment.

0.4 Methodology

The methodology involves training multiple machine learning models (LR, RF, SVM, KNN, MLP) on preprocessed data to predict cervical cancer risk. The Random Forest model is selected as the best-performing model based on AUC performance. Local explainability techniques are then applied to interpret the predictions of the Random Forest model, including LIME and SHAP, to assess the quality of different explanations for cervical cancer risk assessment. Various metrics are computed to determine which explanation method makes the most sense for assessing cervical cancer risk.

0.4.1 Environment

Tested the following code on Python version 3.9.12.

Dependencies required are listed below but following are the main packages: shap, lime, treeinterpreter, dice-ml, shapash, sklearn, numpy, pandas, matplotlib, seaborn, gdown

[1]:
```
!pip install psutil -U kaleido
!pip install shap
!pip install lime
!pip install interpret-community
!pip install alibi
!pip install treeinterpreter
!pip install SALib
!pip install dice-ml
!pip install pip install spectralcluster
!pip install shapash
#!pip install -U kaleido
```

```

0.4.2 Data

Data description: The original paper uses e Cervical cancer risk factors dataset X from the UCI repository, the data is available publicly here. This data contains 858 female patients characterized by D = 35 features including demographic information such as age and number of pregnancies, clinical tests such as Hinselmann, Schiller and Citology, many Sexually Transmitted Diseases such as HPV and AIDS, and diagnosis taken by the patients such as HPV and CIN. For the scope of the project we will be reusing the sample dataset from the original paper.

Implementation code The .csv is stored in GDrive and made available on runtime using gdown library. Majority of time was spent on importing the code from the original paper setting up the Google colab environment.

The dataset comprises demographic information, habits, and historic medical records of 858 patients. Several patients decided not to answer some of the questions because of privacy concerns (missing values). The code uses the ADASYN (AdaptiveSynthetic Sampling) technique in order to balance balanced the dataset by oversampling the minority class. After preprocessing with ADASYN, the new dataset contains 1677 patients. The dataset is split into 80% for training and 20% for testing.

3.2 Risk factors for cervical cancer include:

3.2.1 From the mayo clinic:

- Many sexual partners. The greater your number of sexual partners — and the greater your partner's number of sexual partners — the greater your chance of acquiring HPV.
- Early sexual activity. Having sex at an early age increases your risk of HPV.
- Other sexually transmitted infections (STIs). Having other STIs — such as chlamydia, gonorrhea, syphilis and HIV/AIDS — increases your risk of HPV.
- A weakened immune system. You may be more likely to develop cervical cancer if your immune system is weakened by another health condition and you have HPV.
- Smoking. Smoking is associated with squamous cell cervical cancer.
- Exposure to miscarriage prevention drug. If your mother took a drug called diethylstilbestrol (DES) while pregnant in the 1950s, you may have an increased risk of a certain type of cervical cancer called clear cell adenocarcinoma.

[37]:
```
age_num_sex_partners = px.box(risk_factor_df.
↪sort_values(by="Age",ascending=True), x="age_cat", y="Number of sexual␣
↪partners",
                      color_discrete_sequence=["blue"], points="outliers",
                      category_orders=["Teenager", "Twenties", "Thirties",␣
↪"Forties", "Fifties",
                                       "Seventy and over"])
age_num_sex_partners.update_xaxes(title="Age Category")
age_num_sex_partners.update_yaxes(title="Number of Sexual Partners")
age_num_sex_partners.update_layout(title="Distribution of number of sexual␣
↪partners per age group")
age_num_sex_partners.show()
```

From the scatterplot, it is seen that the number of sexual partners have remained consistent throught out differing age ranges.

[38]:
```
age_num_sex_partners = px.scatter(risk_factor_df, x="Age",
                                  y="Number of sexual partners",
```

```
                                    trendline="ols",
                                    opacity=0.4,
                                    color="Num of pregnancies",
                                    color_continuous_scale="rdbu",)
age_num_sex_partners.update_layout(title="Age vs Number of Sexual Partners")
age_num_sex_partners.show()
```

From the heatmap, we can see that there a correlation coefficent very close to 0, this indicates that, from the data, the number of sexual partners does not have any linear relationship with any of the respective diagnoses. However, we also visually knew that the number of sexual partners remained fairly consistent across age ranges and therefore there are more likely causes of HPV and Cervical Cancer than number of sexual partners with respect to the data.

[39]:
```
diagnoses_num_partner_compare_cols = [label,
                                      'Dx:HPV',
                                      "Number of sexual partners",]
corr_matrix = risk_factor_df[diagnoses_num_partner_compare_cols].corr()
print(corr_matrix)
diagnoses_num_partner_heatmap = px.imshow(corr_matrix,
                                  aspect="auto",
                                  color_continuous_scale="gnbu",
                                  text_auto=True)
diagnoses_num_partner_heatmap.show()
```

```
                            Dx:HPV  Number of sexual partners
Dx:HPV                    1.000000                   0.028646
Number of sexual partners 0.028646                   1.000000
```

3.3 Correlation of diagnoses

Comparing the diagnoses, to see if there is any correlation among them. It's seen that a HPV diagnosis and Cervical Cancer Diagnosis have a correlation of approximately +0.89, this is indicative of a strong positive correlation. In some regard, it can be interprted as a diagnosis of HPV is likely to lead to a diagnosis of Cervical Cancer.

[40]:
```
diagnoses_cols = [label,
                  'Dx:Cancer',
                  'Dx:HPV']
diagnoses_corr_matrix = risk_factor_df[diagnoses_cols].corr()
# print(diagnoses_corr_matrix)
diagnoses_heatmap = px.imshow(diagnoses_corr_matrix, aspect="auto",␣
 ↪color_continuous_scale="tealgrn", text_auto=True)
diagnoses_heatmap.show()
```

3.4 STD's Definitions

3.4.1 Syphilis

Syphillis is a bacterial infection usually spread by sexual contact. The disease starts as a painless sore — typically on the genitals, rectum or mouth. Syphilis spreads from person to person via skin or mucous membrane contact with these sores.After the initial infection, the syphilis bacteria can remain inactive in the body for decades before becoming active again. Early syphilis can be cured, sometimes with a single shot (injection) of penicillin.Without treatment, syphilis can severely damage the heart, brain or other organs, and can be life-threatening. Syphilis can also be passed from mothers to unborn children. Source

3.4.2 HIV/AIDS

HIV (human immunodeficiency virus) is a virus that attacks cells that help the body fight infection, making a person more vulnerable to other infections and diseases. It is spread by contact with certain bodily fluids of a person with HIV, most commonly during unprotected sex (sex without a condom or HIV medicine to prevent or treat HIV), or through sharing injection drug equipment. *If left untreated, HIV can lead to the disease AIDS (acquired immunodeficiency syndrome* [Source](https://www.hiv.gov/hiv-basics/overview/about-hiv-and-aids/what-are-hiv-and-aids#:~:text=HIV%20(human,acquired%20immunodeficiency%20syndrome)

3.4.3 Cervical / Vaginal Condylomatosis

Condyloma or genital warts affect the tissues of the genital area due to infections induced by Human papillomavirus. Source

3.4.4 Vulvo-perineal condylomatosis

It is a benign epithelial proliferative viral lesion that can affect any area of the vulvo-perineal district supported by human papilloma virus (HPV). Source

3.4.5 Genital Herpes

Genital herpes is a common sexually transmitted infection caused by the herpes simplex virus (HSV). Sexual contact is the primary way that the virus spreads. After the initial infection, the virus lies dormant in your body and can reactivate several times a year. Genital herpes can cause pain, itching and sores in your genital area. But you may have no signs or symptoms of genital herpes. If infected, you can be contagious even if you have no visible sores.There's no cure for genital herpes, but medications can ease symptoms and reduce the risk of infecting others. Condoms also can help prevent the spread of a genital herpes infection. Source

3.4.6 HPV

HPV infection is a viral infection that commonly causes skin or mucous membrane growths (warts). There are more than 100 varieties of human papillomavirus (HPV). Some types of HPV infection cause warts, and some can cause different types of cancer. Most HPV infections don't lead to cancer. But some types of genital HPV can cause cancer of the lower part of the uterus that connects to the vagina (cervix). Other types of cancers, including cancers of the anus, penis, vagina, vulva and back of the throat (oropharyngeal), have been linked to HPV infection. These infections are often

transmitted sexually or through other skin-to-skin contact. Vaccines can help protect against the strains of HPV most likely to cause genital warts or cervical cancer. Source

3.4.7 Molluscum Contagisum

Molluscum contagiosum is an infection caused by a poxvirus (molluscum contagiosum virus). The result of the infection is usually a benign, mild skin disease characterized by lesions (growths) that may appear anywhere on the body. Within 6-12 months, Molluscum contagiosum typically resolves without scarring but may take as long as 4 years. The lesions, known as Mollusca, are small, raised, and usually white, pink, or flesh-colored with a dimple or pit in the center. They often have a pearly appearance. They're usually smooth and firm. In most people, the lesions range from about the size of a pinhead to as large as a pencil eraser (2 to 5 millimeters in diameter). They may become itchy, sore, red, and/or swollen. Mollusca may occur anywhere on the body including the face, neck, arms, legs, abdomen, and genital area, alone or in groups. The lesions are rarely found on the palms of the hands or the soles of the feet. Source

The virus that causes molluscum spreads from direct person-to-person physical contact and through contaminated fomites. Fomites are inanimate objects that can become contaminated with virus; in the instance of molluscum contagiosum this can include linens such as clothing and towels, bathing sponges, pool equipment, and toys Source

Someone with molluscum can spread it to other parts of their body by touching or scratching a lesion and then touching their body somewhere else. This is called autoinoculation. Shaving and electrolysis can also spread mollusca to other parts of the body. *Molluscum can spread from one person to another by sexual contact. Many, but not all, cases of molluscum in adults are caused by sexual contact.* Source

3.4.8 Hepatitis B

Hepatitis B is a vaccine-preventable liver infection caused by the hepatitis B virus (HBV). Hepatitis B is spread when blood, semen, or other body fluids from a person infected with the virus enters the body of someone who is not infected. This can happen through sexual contact; sharing needles, syringes, or other drug-injection equipment; or from mother to baby at birth. **Source**

```

We see that the most amount of STD's garnered by any patient, is a total of 4. As from before, we also see that the majority of patients do not have any STD's and aren't diagnosed with cancer and/or HPV. However, there is a small amount of patients who have no STD and have Cervical Cancer and/or HPV. *It should be noted that HPV infections can be sexually transmitted or non-sexually acquired.*

[43]:

3.5 Tests used

Here we observe the number of tests done by patients to determine if they have Cerivcal Cancer / HPV.

The tests used were:

3.5.1 Hinselmann

A colposcopy is a type of cervical cancer test. It lets your doctor or nurse get a close-up look at your cervix — the opening to your uterus. It's used to find abnormal cells in your cervix. Source

3.5.2 Citology

Cytology is the exam of a single cell type, as often found in fluid specimens. It's mainly used to diagnose or screen for cancer. It's also used to screen for fetal abnormalities, for pap smears, to diagnose infectious organisms, and in other screening and diagnostic areas. Source ### Biopsy A cervical biopsy is a procedure to remove tissue from the cervix to test for abnormal or precancerous conditions, or cervical cancer. Source ### Schiller A test in which iodine is applied to the cervix. The iodine colors healthy cells brown; abnormal cells remain unstained, usually appearing white or yellow. Source

[45]:
```
fig = px.histogram(risk_factor_df.query("total_tests>0").
 ↪sort_values(by="total_tests", ascending=True),
                   x="age_cat",
                   facet_col="total_tests",
                   facet_row=label,
                   color_discrete_sequence=["blueviolet"],
                   opacity=0.8)
fig.update_layout(title="Count of women across age groups who have had one or␣
 ↪more test")

fig.show()
```

[46]:
```
fig = px.histogram(risk_factor_df.query("total_tests>0").
 ↪sort_values(by=["total_tests","Dx:HPV"], ascending=True),
                   x="age_cat",
                   facet_col="total_tests",
                   facet_row="Dx:HPV",
                   color_discrete_sequence=["coral"],
                   opacity=0.8)
fig.update_layout(title="Count of women across age groups who have had one or␣
 ↪more test")

fig.show()
```

We see from the ECDF plot, that:

- There is roughly a 95% probability that patients have smoked for less than 10 years
- There is roughly a 99% probability that patients have used IUD's for less than 10 years
- There is roughly a 99% probabilty that patients have used Hormonal Contraceptives for less than 10 years

[47]:
```
fig = px.ecdf(risk_factor_df, x=["Smokes (years)",
                                 "Hormonal Contraceptives (years)",
                                 "IUD (years)"],
              color_discrete_sequence=["crimson", "deepskyblue", "chartreuse"])
fig.update_xaxes(title="Years")
fig.update_layout(title="ECDF Plot")
fig.show()
```

3.6 Proportions of women who have Cervical Cancer / HPV

This represents the proportion of women by age category who were diagnosed with Cervical Cancer/ HPV. It is seen that women in their 30's have the most prevalance of Cervical Cancer and HPV, followed by women in their 20's.

It is also seen that of all the samples taken, approximately 26% are of women in their 30's. With respect to the women who have cervical cancer, approximately 44% of cases are women in their 30's, also, out of the women who have HPV, approximately 39% of women are in their 30's. This is contrasted with 45% of all samples being women in their 20's and only 28% of the women have cancer are in their 20's, HPV is more comparable at 33%.

[48]:
```

3.7 Contraceptive Overview

3.7.1 IUD

IUD stands for Intrauterine Device (basically: a device inside your uterus). It's a small piece of flexible plastic shaped like a T. Sometimes it's called an IUC — intrauterine contraception. Can cost up to $1,300.00 USD

IUDs are divided into 2 types:

- Hormonal IUDs
- Copper IUDs

Both copper IUDs and hormonal IUDs prevent pregnancy by changing the way sperm cells move so they can't get to an egg. If sperm can't make it to an egg, pregnancy can't happen. Source

3.7.2 Hormonal Contraceptive

- The birth control pill works by stopping sperm from joining with an egg. When sperm joins with an egg it's called fertilization.
- The hormones in the pill safely stop ovulation. No ovulation means there's no egg for sperm to fertilize, so pregnancy can't happen.
- The pill's hormones also thicken the mucus on the cervix. This thicker cervical mucus blocks sperm so it can't swim to an egg — kind of like a sticky security guard.
- Can cost up to $50.00 USD. Source

3.8 Hormonal Contraceptives and Cervical Cancer

Women who have used oral contraceptives for 5 or more years have a higher risk of cervical cancer than women who have never used oral contraceptives. The longer a woman uses oral contraceptives, the greater the increase in her risk of cervical cancer. One study found a 10% increased risk for less than 5 years of use, a 60% increased risk with 5–9 years of use, and a doubling of the risk with 10 or more years of use. However, the risk of cervical cancer has been found to decline over time after women stop using oral contraceptives. [Source](https://www.cancer.gov/about-cancer/causes-prevention/risk/hormones/oral-contraceptives-fact-sheet#r12:~:text=Women%20who%20have%20used,stop%20using%20oral%20contraceptives%

The usage of hormonal contraceptives is significantly higher than the usage of IUD's, this can most likely be attributed to it's low cost and easy accessibility

[50]:
```

6.0.1 Model

Original Paper: Ayad, Wafa & Bonnier, Thomas & Bosch, Benjamin & Read, Jesse & Parbhoo, Sonali. (2023). Which Explanation Makes Sense? A Critical Evaluation of Local Explanations for Assessing Cervical Cancer Risk Factors Ecole polytechnique. 1-50. https://www.researchgate.net/profile/Wafa-Ayad/publication/374061335_Which_Explanation_Makes_Sense_A_Critical_Evaluation_of_Local_Explanati
Explanation-Makes-Sense-A-Critical-Evaluation-of-Local-Explanations-for-Assessing-Cervical-Cancer-Risk-Factors-Ecole-polytechnique.pdf

Original paper repo: https://github.com/cwayad/Local-Explanations-for-Cervical-Cancer

Model descriptions The project employs a variety of machine learning models and local explanation techniques to interpret predictions and assess the risk factors associated with cervical cancer. The models utilized include:

1. **Logistic Regression (LR)**: A linear model that estimates probabilities using a logistic function, making it suitable for binary classification tasks like predicting cervical cancer risk.
2. **Random Forest (RF)**: A popular ensemble learning method that constructs multiple decision trees during training and outputs the mode of the classes (classification) or mean prediction (regression) of the individual trees. Random forests are known for their robustness and ability to handle high-dimensional data.
3. **Multi-Layer Perceptron (MLP)**: A type of feedforward artificial neural network composed of multiple layers of nodes, each layer fully connected to the next one. MLPs are capable of learning complex patterns in data and are commonly used for classification tasks.
4. **Support Vector Machine (SVM)**: A supervised learning algorithm that constructs a hyperplane or set of hyperplanes in a high-dimensional space, which can be used for classification, regression, or other tasks. SVMs are effective in high-dimensional spaces and are particularly well-suited for cases where the number of dimensions exceeds the number of samples.
5. **K-Nearest Neighbors (KNN)**: A non-parametric, lazy learning algorithm used for classification and regression tasks. KNN works by finding the k-nearest neighbors of a given data point and making predictions based on their class labels or feature values.

For interpreting the predictions of these models, various local explanation techniques are employed, including:

1. **LIME (Local Interpretable Model-agnostic Explanations)**: A method for explaining the predictions of any classifier by approximating it locally with an interpretable model.
2. **SHAP (SHapley Additive exPlanations)**: A game-theoretic approach to explain the output of any machine learning model. SHAP values provide a unified measure of feature importance.
3. **DiCE (Diverse Counterfactual Explanations)**: A framework for generating diverse counterfactual explanations for individual predictions of machine learning models.
4. **Tree Interpreter**: A technique specifically designed for interpreting decision trees by calculating feature importances and contributions to predictions.
5. **Local Surrogates**: A method for creating a simpler, interpretable model that approximates the behavior of a complex black-box model locally.

6.0.2 Implementation code

Currently implemented all the basic ML models: RF, SVM, LR, KNN, MLP on the given dataset and compared the metrics for each of the model based on F1 score, AUROC, Accuracy, Precision and Recall. Please find below for more details. The local explanation techniques are being currently worked on.

Training ### Computational requirements The computational requirements for the project include:

1. **Hardware Specifications**:

- CPU: A multi-core processor with sufficient computational power for training machine learning models. A CPU with at least 4 cores and a clock speed of 2.5 GHz or higher is recommended.
- RAM: Adequate RAM to handle the dataset size and model training. A minimum of 8 GB RAM is recommended for handling the preprocessing and training tasks efficiently.

2. **Software Tools**:

- Python Environment: Python 3.x environment for running the project code. Anaconda distribution is recommended for managing Python dependencies.
- Libraries: Required Python libraries include scikit-learn, TensorFlow or PyTorch (for deep learning models), SHAP, Pandas, NumPy, and gdown for downloading datasets from Google Drive.
- IDE or Text Editor: A code editor such as Jupyter Notebook or Google Colab for running Python scripts and executing code cells interactively.

3. **Storage Requirements**:

```
- Dataset Storage: Sufficient storage space to store the dataset file (.csv format) and any ad
- Model Checkpoints: Storage space to save model checkpoints during training to resume trainin
```

4. **Network Connectivity**:

- Stable Internet Connection: A stable internet connection is necessary for downloading the dataset from the UCI repository and accessing files stored on Google Drive. It is also required for accessing external resources and libraries.

5. **Training Time**:

- Model training time varies depending on the selected machine learning algorithms and the complexity of the dataset. Training multiple machine learning models (LR, RF, SVM, KNN, MLP) and then evaluation the local explainations may require several hours to complete. We are working on trying to reduce the computation models by saving the pretrained models and then using it in the Jupyter notebook.
- Utilizing hardware accelerators such as GPUs can significantly reduce training time for deep learning models. If available, a GPU with CUDA support is recommended for faster training.

6. **High-Performance Computing (HPC)**:

- For future experimentation involving computationally intensive tasks, access to high-performance computing (HPC) clusters or cloud-based computing resources may be beneficial. These resources can accelerate model training and experimentation by distributing tasks across multiple nodes or GPUs.

Overall, the project requires standard computational resources including a CPU with sufficient processing power, an adequate amount of RAM, storage space for datasets and model checkpoints, stable internet connectivity, and potentially access to high-performance computing resources for faster training.

6.0.3 Implementation code

Currently the different models: RF, SVM, LR, KNN, MLP have been trained and evaluated below along with a few local explanation techniques. The local explanation techniques like SHAP (KSHAP, SSHAP) require around 1-2 hours of CPU runtime - we have pretrained these models and stored the generated shap values to reduce time for execution of the jupyter notebook.

Some hyperparams used are : Cross validation is 10 for KNN and 5 for SVM. We use GridSearchCV to calculate the best params for Logistic regression, KNN and SVM. Some of the observation from below ablations are mentioned below but for the sake of reproducibility of the paper we use the result with ADASYN sampled data which is:

LogisticRegression(C=268.2695795279727), KNeighborsClassifier(n_neighbors=1), SVC(C=100.0, gamma=0.001)

The computation for KSHAP for example takes around 336 iterations each one taking around 10s/iteration (for MLP model)

7 Comparing different models: RF, SVM, LR, KNN, MLP

7.1.1 Evaluation

Metrics descriptions

7.1.2 Interpretation of the results

- TP: True Positive, these are the values that are positive and were predicted positive
- FP: False Positive, The values which are negative but were wrongly predicted as positive
- TN: True Negative, these are the values that are negative and were predicted negative
- FN: False Negative, The values which are positive but were wrongly predicted as negative

Precision

$$precision = \frac{TP}{TP + FP}$$

This metric measures the actual positive outcomes out of the total predicted positive outcomes. It attempts to identify the proportion of positive identifications that were correct. The Logistic Regression model and Support Vector Classifer model performed equally well with a precision score of 99.41%.

In the context of diagnoising cervical cancer, this is metric would not be the most ideal to measure performance, as a negative case being labelled as a positive case is easily solved with confirmatory tests. However, one has to also consider the emotional and mental issues brought upon by being diagnosed with cervical cancer, as this can have a lingering effect even after having confirmatory tests. These tests should be done as soon as possible, as there may be another underlying illness that brought them to see a healthcare professional in the first place.

Recall

$$recall = \frac{TP}{TP + FN}$$

This metirc measures the correctly positive predicted outocmes of the total number of positive outcomes. It answers the question of what proportions of actual positives were identified correctly. The Logistic Regression model and Support Vector Classifer model performed equally well with

a recall score of 99.4%. In terms of measuring performance of the model, this is the metric that should be highly considered.

In the context of diagnosing cervical cancer, we want to reduce the number of false negatives (Actual positive cases labelled as negative cases) as much possible. If an actual positive case is labelled as negative, this has serious consequecnes as the patient would go about their life without actually receiving potentially life saving treatment.

There are many reasons why a cancer can go misdiagnosed, these include: * The symptoms,especially in the early stages being mistaken for some other type of less serious illness. * The actual test adminstered by a healthcare professional may give the wrong diagnosis

The 5-year survival rate tells you what percent of people live at least 5 years after the cancer is found. Percent means how many out of 100. The 5-year survival rate for all people with cervical cancer is 66%. Source

Survival rates also depend on the stage of cervical cancer that is diagnosed. When detected at an early stage, the 5-year survival rate for people with invasive cervical cancer is 92%. About 44% of people with cervical cancer are diagnosed at an early stage. If cervical cancer has spread to surrounding tissues or organs and/or the regional lymph nodes, the 5-year survival rate is 58%. If the cancer has spread to a distant part of the body, the 5-year survival rate is 18%. Source

It is clearly important and evident that a correct diagnosis and early treatment is the best possible way to ensure that a patient has a high chance of surviving.

F1 Score

$$F1Score = \frac{TP}{TP + \frac{FN+FP}{2}}$$

The F1 score is defined as the harmonic mean of precision and recall. Therefore, a high F1 score means both a high precision and recall, same for low and a medium score if one score is high and the other is low.

The Logistic Regression model and Support Vector Classifer model performed equally well with an accuracy score of 99.4%

Accuracy

$$Accuracy = \frac{TP + TN}{TP + FP + TN + FN}$$

The Logistic Regression model and Support Vector Classifer model performed equally well with an accuracy score of 99.4%

AUROC AUC - ROC curve is a performance measurement for the classification problems at various threshold settings. ROC is a probability curve and AUC represents the degree or measure of separability. It tells how much the model is capable of distinguishing between classes. Higher the AUC, the better the model is at predicting 0 classes as 0 and 1 classes as 1. By analogy, the Higher the AUC, the better the model is at distinguishing between patients with the disease and no disease. Source

Consistency Metric: Compares explanations attributed to the same instance by different feature importance-based methods, enhancing user confidence in model predictions. This is done through

computing an L2 distance between pairs of explanations. If two different methods attribute similar feature importance to the same instance or set of instances, the user's confidence and trust in the model's predictions increases.

Stability Metric: Compares explanations for instances with similar feature values and predictions, ensuring consistent attributions. In order to perform the stability analysis this uses the local Lipschitz metric for explanation stability -

Compactness Metric: Measures the number of features needed to explain a certain percentage of the prediction, aiding in understanding model decisions. This can be obtained by fixing the percentage we want to reach and compute the number of features needed to explain that fixed percentage of the prediction.

Faithfulness Metric (ROAR): Involves iteratively removing features, retraining the model, and evaluating changes in accuracy or feature importance, assessing the impact of feature removal on model performance.

Implementation code

The evaluation metrics are implemented using Python libraries such as scikit-learn and SHAP.

For the Consistency Metric, L2 distance computation between pairs of explanations can be achieved using numpy.

The Stability Metric can be implemented by comparing explanations for instances with similar feature values and predictions using scikit-learn.

The Compactness Metric can be calculated by fixing a percentage of the prediction and computing the number of features needed to explain that percentage using pandas and numpy.

The Faithfulness Metric (ROAR) can be implemented by iteratively removing features, retraining the model, and evaluating changes in accuracy or feature importance using scikit-learn and pandas.

8.2.1 Results

Table of results

Experiments	Original Paper Expectations (Hypothesis and Results)	Results	Discussions
Trained five different models - LR, RF, MLP, SVM and KNN with CV=10	The paper mentioned RF as the model which performed as the best ML model for cervical cancer	RF, LR and MLP produced the best result with a score of 1 on F1, Accuracy, Precision, Recall and AUROC	
Consistency between pairs of explainable AI models	Tree SHAP and Sampling SHAP is the most consistent pair, while Local Surrogate and DiCE is the least consistent pair.	We see that Local Surrogate and DiCE is the least consistent pair with a score of 1.4 and KSHAP and SSHAP having the least score of 0.025	All SHAP models have similar scores and are quite consistent
Faithfulness - removal of features doesn't affect model's accuracy	LIME is seen as the model with most faithful explanations while TreeSHAP has the lowest faithfulness score	We see LIME perform well upto 40% of feature while the accuracy of DICE model falls drastically till removal of 30% of features	The results were not identical primarily becuase the original solution was using a csv to which we didnt have access to validate and use the data present in it.
HPV is the most important risk factor for cervical cancer	All SHAP models primarily rely on 1 feature and that is HPV presence to predict cervical cancer	We too see a similar result where SHAP models heavily depend on 1 feature but Surrogates and DICE use 4 to 10 different features to make their predictions	
Stability of explanations	LIME, KSHAP and local surrogates are found to be least stable with a lot of variability	LIME, KSHAP and local surrogates are found to be least stable with a lot of variability in our results as well	

Ablation Study

1. Carried out different sampling techniques like Random over sampler, SMOTE, using original da

2. Used MLP instead of RF as mentioned in paper and we were able to justify similar outcomes wh

8.2.2 Discussion

1. Implications of the experimental results, whether the original paper was reproducible, and if it wasn't, what factors made it irreproducible

   Most of the results mentioned in the original paper were reproducible but some of them didnt exactly match the values mentioned in the paper. This was probably because there were no clear steps mentioned on how they had reproduced the results. Also some of the steps had links to person drive and csv files to which we couldnt gain access to making it difficult to verify the data in those sources resulting in additional preprocessing steps and assumptions to be made.

2. What was easy?

   The dataset and preprocessing steps were easy- because the dataset used was not huge (contained around 850 records and was around 65KB in size) and was easy to load and process as compared to some other datasets which could span over 1GB of size.

3. What was difficult?

   The explainable AI (XAI) steps were not clearly structured in an ordered manner due to which some of the steps failed and additional preprocessing steps needed to be added to make sure that the data was compatible for processing. Also for some of the XAI models there were mentions of some csv files which seemed to point to personal drive links and were not accessible to verify and utilize the same for reproduction of the results. This made it slightly more difficult to reproduce exact results and some assumptions had to be made (like the csv mentioned was the same as the dataset from UCI)

4. Recommendations to the original authors or others who work in this area for improving reproducibility

   The refactoring and some of the ablations carried out in this project will definitely help the original authors and anyone else working on this project to have a structured way of executing the steps. The explainable code needs to be refactored in the original solution to achieve desirable results. Also personal drive links need to be replaced by public ones and libraries like gdown should be used to make available any extra datasets or csvs being used which are not mentioned in the original paper.
